NAG Library Function Document

nag_1d_spline_fit_knots (e02bac)

1 Purpose
nag_1d_spline_fit_knots (e02bac) computes a weighted least squares approximation to an arbitrary set of data points by a cubic spline with knots prescribed by you. Cubic spline interpolation can also be carried out.

2 Specification

```c
#include <nag.h>
#include <nage02.h>
void nag_1d_spline_fit_knots (Integer m, const double x[], const double y[],
                           const double weights[], double *ss, Nag_Spline *spline, NagError *fail)
```

3 Description

nag_1d_spline_fit_knots (e02bac) determines a least squares cubic spline approximation \( s(x) \) to the set of data points \( (x_r, y_r) \) with weights \( w_r \), for \( r = 1, 2, \ldots, m \). The value of \( \text{spline} = n = \tilde{n} + 7 \), where \( \tilde{n} \) is the number of intervals of the spline (one greater than the number of interior knots), and the values of the knots \( \lambda_5, \lambda_6, \ldots, \lambda_{\tilde{n}+3} \), interior to the data interval, are prescribed by you.

\( s(x) \) has the property that it minimizes \( \sum \epsilon_r \), the sum of squares of the weighted residuals \( \epsilon_r \), for \( r = 1, 2, \ldots, m \), where

\[
\epsilon_r = w_r(y_r-s(x_r)).
\]

The function produces this minimizing value of \( \sum \epsilon_r \) and the coefficients \( c_1, c_2, \ldots, c_q \), where \( q = \tilde{n} + 3 \), in the B-spline representation

\[
s(x) = \sum_{i=1}^{q} c_i N_i(x).
\]

Here \( N_i(x) \) denotes the normalized B-spline of degree 3 defined upon the knots \( \lambda_i, \lambda_{i+1}, \ldots, \lambda_{i+4} \).

In order to define the full set of B-splines required, eight additional knots \( \lambda_1, \lambda_2, \lambda_3, \lambda_4 \) and \( \lambda_{\tilde{n}+4}, \lambda_{\tilde{n}+5}, \lambda_{\tilde{n}+6}, \lambda_{\tilde{n}+7} \) are inserted automatically by the function. The first four of these are set equal to the smallest \( x_r \) and the last four to the largest \( x_r \).

The representation of \( s(x) \) in terms of B-splines is the most compact form possible in that only \( \tilde{n} + 3 \) coefficients, in addition to the \( \tilde{n} + 7 \) knots, fully define \( s(x) \).

The method employed involves forming and then computing the least squares solution of a set of \( m \) linear equations in the coefficients \( c_i (i = 1, 2, \ldots, \tilde{n} + 3) \). The equations are formed using a recurrence relation for B-splines that is unconditionally stable (Cox (1972), de Boor (1972)), even for multiple (coincident) knots. The least squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotations (Gentleman (1974) and Gentleman (1973)). This requires only one equation to be stored at a time. Full advantage is taken of the structure of the equations, there being at most four nonzero values of \( N_i(x) \) for any value of \( x \) and hence at most four coefficients in each equation.

For further details of the algorithm and its use see Cox (1974), Cox (1975) and Cox and Hayes (1973).

Subsequent evaluation of \( s(x) \) from its B-spline representation may be carried out using nag_1d_spline_evaluate (e02bbc). If derivatives of \( s(x) \) are also required, nag_1d_spline_deriv (e02bcc) may be used. nag_1d_spline_intg (e02bdc) can be used to compute the definite integral of \( s(x) \).

5 Arguments

1: \( m \) – Integer

*Input*

*On entry:* the number \( m \) of data points.

*Constraint:* \( m \geq m_{dist} \geq 4 \), where \( m_{dist} \) is the number of distinct \( x \) values in the data.

2: \( x[m] \) – const double

*Input*

*On entry:* the values \( x_r \) of the independent variable (abscissa), for \( r = 1, 2, \ldots, m \).

*Constraint:* \( x_1 \leq x_2 \leq \ldots \leq x_m \).

3: \( y[m] \) – const double

*Input*

*On entry:* the values \( y_r \) of the of the dependent variable (ordinate), for \( r = 1, 2, \ldots, m \).

4: \( \text{weights}[m] \) – const double

*Input*

*On entry:* the values \( w_r \) of the weights, for \( r = 1, 2, \ldots, m \). For advice on the choice of weights, see the e02 Chapter Introduction.

*Constraint:* \( w_r > 0 \), for \( r = 1, 2, \ldots, m \).

5: \( \text{ss} \) – double *

*Output*

*On exit:* the residual sum of squares, \( \theta \).

6: \( \text{spline} \) – Nag_Spline *

Pointer to structure of type Nag_Spline with the following members:

\( n \) – Integer

*Input*

*On entry:* \( \tilde{n} + 7 \), where \( \tilde{n} \) is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range \( x_1 \) to \( x_m \)) over which the spline is defined.

*Constraint:* \( 8 \leq n \leq m_{dist} + 4 \), where \( m_{dist} \) is the number of distinct \( x \) values in the data.
6 Error Indicators and Warnings

**NE_ALLOC_FAIL**

Dynamic memory allocation failed.

**NE_INT_ARG_LT**

On entry, `spline[n]` must not be less than 8: `spline[n] = ⟨value⟩`.

**NE_KNOTS_DISTINCT_ABSCLI_CONS**

Too many knots for the number of distinct abscissae, `mdist`: `spline[n] = ⟨value⟩`, `mdist = ⟨value⟩`. These must satisfy the constraint `spline[n] ≤ mdist + 4`.

**NE_KNOTS_OUTSIDE_DATA_INTVL**

On entry, user-specified knots must be interior to the data interval, `spline[4]` must be greater than `x[0]` and `spline[5]` must be less than `x[m - 1]`: `spline[4] = ⟨value⟩`, `x[0] = ⟨value⟩`, `spline[5] = ⟨value⟩`, `x[m - 1] = ⟨value⟩`.

**NE_NOT_INCREASING**

**NE_SW_COND_FAIL**

The conditions specified by Schoenberg and Whitney fail. The conditions specified by Schoenberg and Whitney (1953) fail to hold for at least one subset of the distinct data abscissae. That is, there is no subset of `spline[n]` strictly increasing values, `x[r0]`, `x[r1]`, ..., `x[r5]`, among the abscissae such that

- `x[r0] < spline[0] < x[r4]`,
- `x[r1] < spline[1] < x[r5]`,
- ...

The NAG error argument (see Section 3.6 in the Essential Introduction).
This means that there is no unique solution: there are regions containing too many knots compared with the number of data points.

**NE_WEIGHTS_NOT_POSITIVE**

On entry, the weights are not strictly positive: \(weights[[\text{value}]] = \langle \text{value} \rangle\).

### 7 Accuracy

The rounding errors committed are such that the computed coefficients are exact for a slightly perturbed set of ordinates \(y_r + \delta y_r\). The ratio of the root-mean-square value for the \(\delta y_r\) to the root-mean-square value of the \(y_r\) can be expected to be less than a small multiple of \(\kappa \times \text{machine precision}\), where \(\kappa\) is a condition number for the problem. Values of \(\kappa\) for 20-30 practical datasets all proved to lie between 4.5 and 7.8 (see Cox (1975)). (Note that for these datasets, replacing the coincident end knots at the endpoints \(x_1\) and \(x_m\) used in the function by various choices of non-coincident exterior knots gave values of \(\kappa\) between 16 and 180. Again see Cox (1975) for further details.) In general we would not expect \(\kappa\) to be large unless the choice of knots results in near-violation of the Schoenberg–Whitney conditions.

A cubic spline which adequately fits the data and is free from spurious oscillations is more likely to be obtained if the knots are chosen to be grouped more closely in regions where the function (underlying the data) or its derivatives change more rapidly than elsewhere.

### 8 Parallelism and Performance

Not applicable.

### 9 Further Comments

The time taken by nag_1d_spline_fit_knots (e02bac) is approximately \(C \times (2m + \bar{n} + 7)\) seconds, where \(C\) is a machine-dependent constant.

Multiple knots are permitted as long as their multiplicity does not exceed 4, i.e., the complete set of knots must satisfy \(\lambda_i < \lambda_{i+4}\), for \(i = 1, 2, \ldots, \bar{n} + 3\), (see Section 6). At a knot of multiplicity one (the usual case), \(s(x)\) and its first two derivatives are continuous. At a knot of multiplicity two, \(s(x)\) and its first derivative are continuous. At a knot of multiplicity three, \(s(x)\) is continuous, and at a knot of multiplicity four, \(s(x)\) is generally discontinuous.

The function can be used efficiently for cubic spline interpolation, i.e., if \(m = \bar{n} + 3\). The abscissae must then of course satisfy \(x_1 < x_2 < \cdots < x_m\). Recommended values for the knots in this case are \(\lambda_i = x_{i-2}\), for \(i = 5, 6, \ldots, \bar{n} + 3\).

### 10 Example

Determine a weighted least squares cubic spline approximation with five intervals (four interior knots) to a set of 14 given data points. Tabulate the data and the corresponding values of the approximating spline, together with the residual errors, and also the values of the approximating spline at points halfway between each pair of adjacent data points.

The example program is written in a general form that will enable a cubic spline approximation with \(\bar{n}\) intervals (\(\bar{n} - 1\) interior knots) to be obtained to \(m\) data points, with arbitrary positive weights, and the approximation to be tabulated. Note that nag_1d_spline_evaluate (e02bbc) is used to evaluate the approximating spline. The program is self-starting in that any number of datasets can be supplied.
